REVISIONS – SealGuard – GO-DELEON-ILAO

- Sharpen the problem context and significance; the opening rationale was too general; Tie it to procurement-contract authenticity and explain conretely what value residents get from transparent procurement documents
- Clarify and consistently state the document scope; The study claims procurement contracts only, yet folders such as Purchase Orders, MOA/MOU, and the generic "contract" label suggest broader use; Reflect on scope and state it consistently in the system and in the paper
- Cover both physical (wet-signature) and digital document flows; Explain how documents actually reach the system; printed, wet-signed, scanned and uploaded versus born-digital PDFs
- Provide the current barangay process and the proposed process; presented process flow seemed to be too "linear" to be true (no branching); state which documents are uploaded and at what stage
- Use the correct term for user groups; "locale one, locale two" needs to be referred differently; Use strata or user group 1 (or 2) instead
- Improve the landing page of the different users (Admin from staff); Justify every placement as a design decision tied to how the barangay actually do things (like why Trash sits directly under All Documents)
- Justify the Trash/delete function; Define the criteria clearly as to when would a staff member delete a record/document
- Explain and fix the versioning logic; Duplicate detection currently relies on the file name alone; improve the logic; Add a preview of the incoming version before the upload is confirmed
- Define what happens when a system-issued (stamped/QR) PDF is re-uploaded as a new revision; System showed an "already authenticated" message, but the developers could not explain its basis; document the logic and discuss in paper thoroughly
- Fix the Title field on upload; A typed title is overwritten by the file name; Either remove the field or make the typed title take effect
- Fix folder handling; Let users choose the folder at upload time, show the current folder in the All view, and rename "Add to Folder" to "Move to Folder" for documents already in a folder (reserve the "Add" for unsorted documents
- Explain the SGPDF scenario; Panel found the design to be sensible once it was clear that a copy is unusable without approved access; tell that story in the paper
- Make the access-request note required; It was pointed out that a cybersecurity leaning system should not assume the requester is known

- Provide a basis for the access-duration options; Explain why the options 1 hour, 24 hours and 3 days, and consider whether a shorter, a finer-grained view window is needed given the large jump between 1 hour and 24 hours
- The system should have a feature addressing the needs of residents who cannot visit the barangay
- Provide a lightweight account creation to view/download published documents, so there would be audit trais and analytics to it; should be complete with features of verifying that the user creating the account is a citizen of the barangay, or at least a real person
- Clearly define the rights of an Admin versus a staff; As presented, both can manage access requests; anchor the design decision to barangay workload, or restrict the function to admin if it has something to do with security
- Improve QR verification behavior; should provide true in-context message (system should say the QR is invalid, not in the records, unrecognizable, etc); also, state as a limitation that a matching QR identifies the page only (the resident still has to compare the printed content)
- Explain how alpha test cases were derived and reconcile the numbers; Explain the basis of the alpha tests; Reconcile figures such as “83” against the population (30 residents + 15 officials = 45); Discuss results in narrative
- Show the computation of means and timing/efficiency measures; State the formula and basis for the means and millisecond figures, and how efficiency was determined
- Report compatibility results per browser and device; Show the result for each browser and specify the mobile devices used
- Explain how stress test data was captured; Explain why the first attempt failed ans was then reset, and how the stress-test figures were obtained
- Classify tests as functional or non-functional; Label which tests are functional (e.g., login, processing) and which are non-functional, and present them accordingly
- Declare simulated/emulated tests and the test environment; State clearly which tests used simulation, emulators, or third-party tools versus actual hardware or an acutal server, and describe the environment (VM or a separate server)
- Present the complete UAT tables, not only overall means
- Rewrite the conclusion; Write continuous paragraphs that map the Ch4 resultss to the attainment of each objective, without objective-based separators or bold subheadings (not bulleted)
- Make the system architecture consistent; The architecture diagram appears 3 times in same versions but different from the one presented in the slides

- Use correct DFD notation; improve the DFD
- Improve the writing of the manuscript; fix inconsistent formatting; place figures near their references, format equations properly; use declarative tense whenever appropriate
